Cloud Extensibility (Project Firefly)

Project Firefly

A complete design, application and runtime framework for building 3rd-party Cloud Native Applications that extend the functionality of Adobe solutions and run on our infrastructure.

`$ aio app create`

From CLI

Command-Line Interface

To Visual Editor

To Code

**To Custom App
Deployed in Adobe
Products**

Who is this for?

System Integrator Developers

Developers who work at System Integrators and are typically specialized on integrating and extending Adobe enterprise solutions (AEM, Magento, Campaign, Marketo, etc). They typically know a lot about our developer tools and capabilities.

Enterprise Developers

Developers working for our enterprise customers, part of IT or some other in-house developer department. Their knowledge about the Adobe ecosystem may be nascent.

Project Firefly Product Principles

Make Hard Things Easy

Everything You Need
Is In The Box

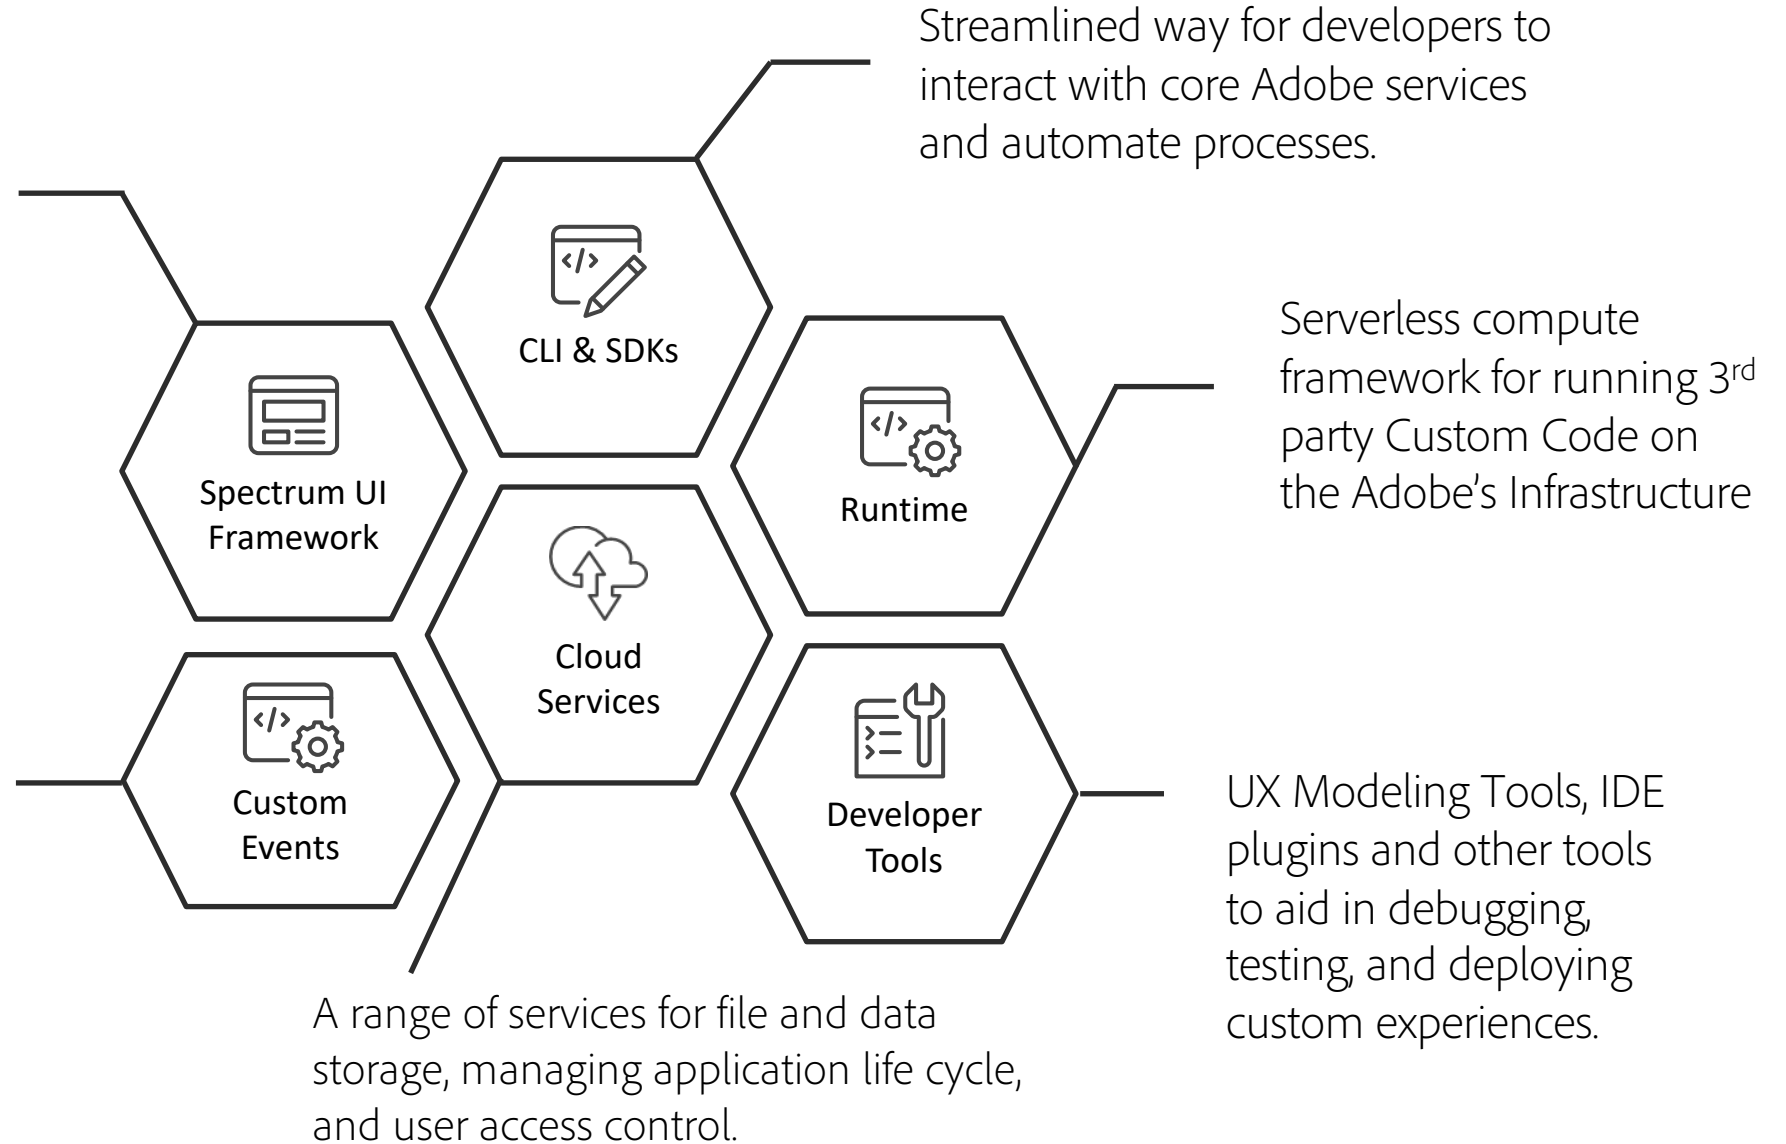

Extendable, It Grows With
Your Needs

Project Firefly Components

React-based UI framework for creating experiences that feel native alongside Adobe products.

Publish and consume custom events, with support for webhooks and journaling

Project Firefly Use Case

Use Case | Asset Microservices Custom Processing Profile

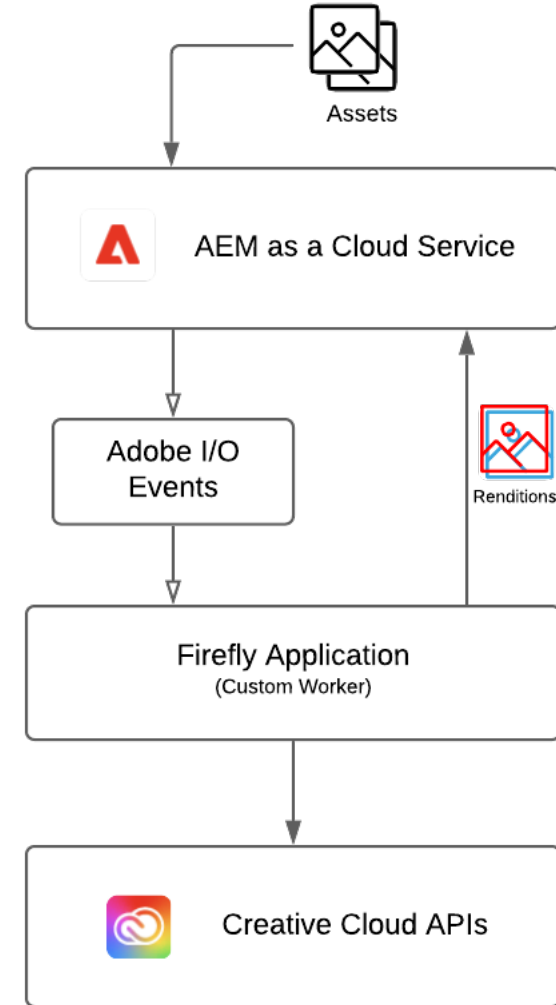

As a customer using AEM as a Cloud Service, I want to easily manage my assets and run configurable and customizable asset workflows at scale.

Challenge

Customer want to easily manage assets and run custom asset workflows at scale while maximizing (and not impacting) the performance and responsiveness of their AEM DAM.

Solution

Asset microservices enabled AEM developers to create custom processing profiles in the form of headless Firefly applications with built-in SDKs that customizes transformation and enhancement of digital assets. Customers can access and use these custom processing profiles in AEM for their assets.

Use Case | Server Side Rendering

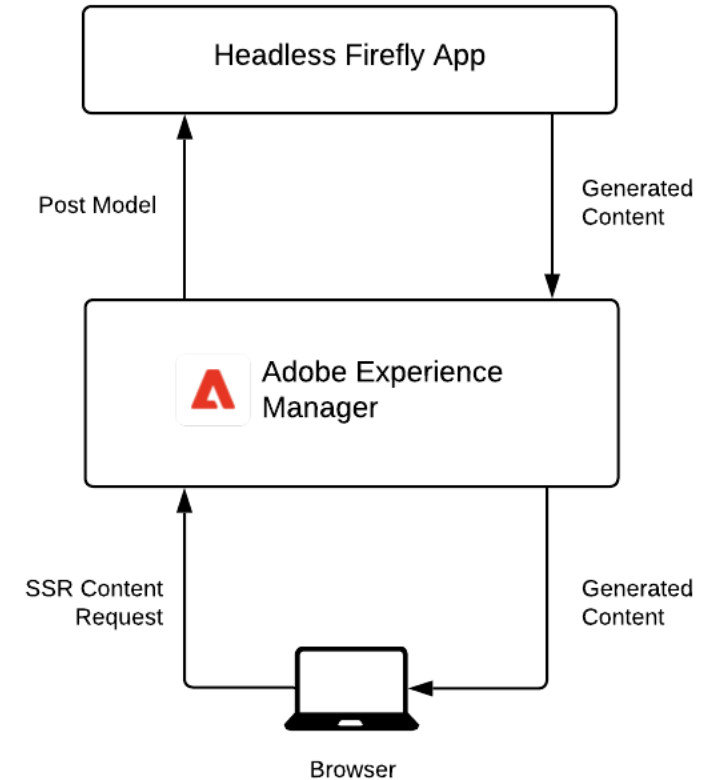

As a customer using building a SPA, I want to leverage content in AEM without impacting the load time for my application.

Challenge

Customer would like to build a Single Page Application (SPA) to offer rich and dynamic experience. However, this often requires the client to load the content upfront and minimize the amount of communication needed between the client and the server, which can lead to long initial load time.

Solution

Developer built a headless Firefly app to optimize initial load times by rendering certain content server-side, then passing to client.

Use Case | Event Driven Integration

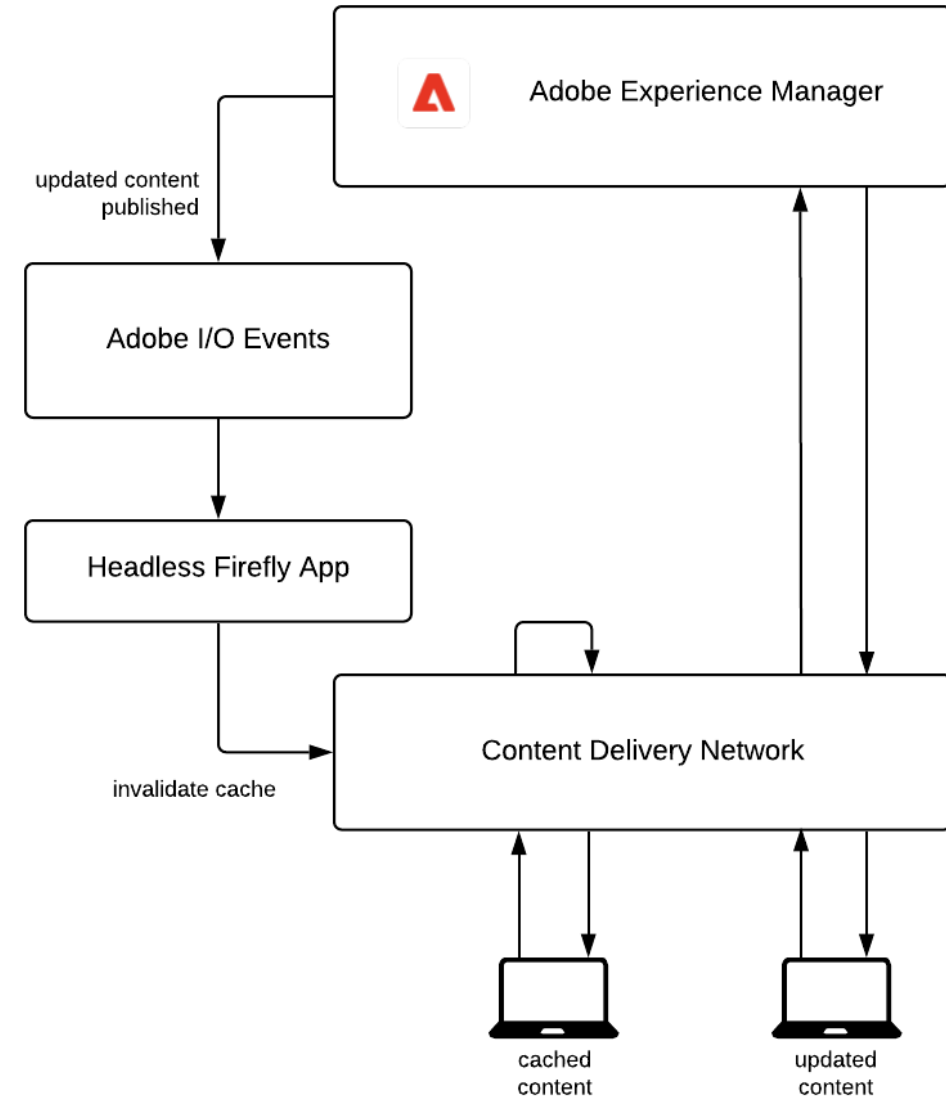

As a customer using AEM as a Cloud Service, I want my asset changes to be reflected immediately.

Challenge

Customer would like to see all web asset changes reflected immediately on published pages. Currently, with their Dynamic Media set up, the customer needs to either manually clear the cache upon every new asset published, or to wait until the cache expires by itself, which may take up to 10 hours.

Solution

Developer built a headless event-driven Firefly application that listens to AEM Asset publish events, and upon assets published, trigger cache invalidation at the CDN level for this asset. This Firefly application allows the customer to achieve desired outcome without any impact to AEM performance nor additional AEM deployment.

Use Case | AEM Asset Migration

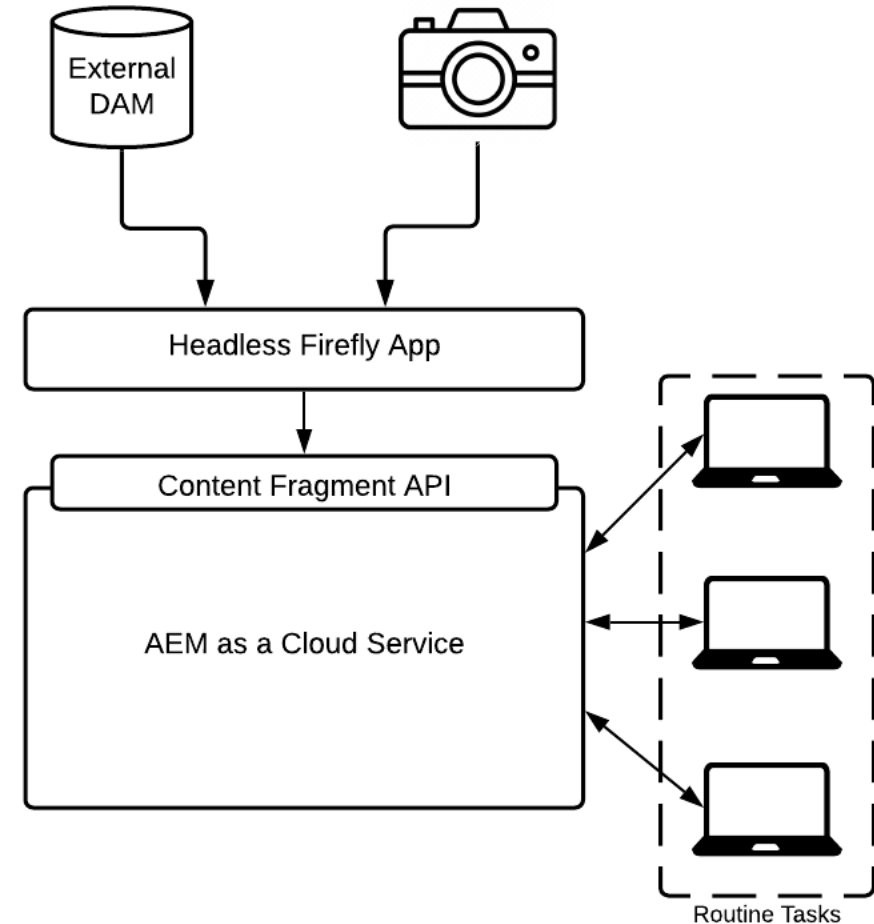

As a customer, I want to migrate all my assets that are currently in an external DAM into AEM.

Challenge

Migrating assets into AEM by running a custom in-process application consumes valuable AEM resources. Customers need a way to bulk upload assets every few days without affecting other routine tasks running on AEM.

Solution

Developer offload the migration process to a headless Firefly application that uses the Content Fragment API to transfer assets from the external DAM into AEM.
